

Method of double green manuring with oil radish and winter rye in organic farming involves sowing oil radish as a post-harvest green manure by the end of July, at a rate of 20–25 kg/ha, following the harvest of cereals, legumes or industrial crops. At the end of October, winter rye seeds are broadcast-sown over the surface of the oil radish plant biomass at a rate of 160 –180 kg/ha, and combined disc tillage is carried out to a depth of 8–10 cm to incorporate the winter rye seeds into the soil together with the cut oil radish plant biomass.
