

Disposable self-locking device for retracting and holding wound edges during surgery, consisting of two working parts, one of which secures the wound edges and the other holds them in place. Designed disposable and self-locking, its holding working part is made in the form of a base plate to which two movable support legs are hingedly attached by fasteners, with the possibility of adjusting the width between them, with a self-locking effect due to its flexibility and ability to slide under the separated mucosal-osseous flap. The part that secures the edges of the wound is designed as an elastic band, the ends of which are inserted into the slots of the base plate with the formation of an arc, the size of which is adjusted by securing the ends of the elastic band in the slots of the base plate to the appropriate size, taking into account the architectonics of the patient's bone and the size of the surgical wound.
